

DR. FABRY: THANK YOU. IT'S A REAL PLEASURE TO BE HERE.

17 TODAY I'M GOING TO TALK ABOUT THE
18 POSSIBLE CONSEQUENCES OF GLOBAL WARMING AND OCEAN
19 ACIDIFICATION ON MARINE ECOSYSTEMS.

20 WE KNOW THAT THE OCEAN IS GETTING WARMER,
21 AND IT'S TAKING UP MORE ANTHROPOGENIC CO₂. THIS
22 CLIMATE FORCING HAS OTHER ENVIRONMENTAL EFFECTS,
PARTICULARLY
23 ON THE UPPER WATER COLUMN WHICH IN THE FUTURE WILL BECOME
MORE

24 STRATIFIED, WILL HAVE LOWER NUTRIENT AVAILABILITY,
25 DECREASED OXYGEN, LOWER PH, LOWER CARBONATE ION

0420

1 CONCENTRATION, AND A LOWER CARBONATE SATURATION
2 STATE. THIS ENVIRONMENTAL FORCING WILL HAVE
3 EFFECTS ON THE PHYSIOLOGICAL PROCESSES OF ORGANISMS;
4 PHYSIOLOGICAL PROCESSES SUCH AS
5 PHOTOSYNTHESIS, CALCIFICATION, NITROGEN FIXATION,
6 GROWTH AND REPRODUCTION, AND
7 ULTIMATELY THE FITNESS AND THE SURVIVAL OF THE
8 ORGANISM. THESE PHYSIOLOGICAL EFFECTS THEN CAN
9 PROPAGATE UP TO THE ECOSYSTEM LEVEL, AND THERE CAN BE
10 ECOSYSTEM IMPACTS SUCH AS POTENTIAL CHANGES IN THE OVERALL
11 PRODUCTIVITY OF A REGION, CHANGES IN SPECIES SUCCESSION,
12 ALTERATIONS TO FOOD WEBS, SHIFTS IN SPECIES ABUNDANCES AND
13 THEIR DISTRIBUTIONS, AND ALSO IMPACTS ON BIOGEOCHEMICAL
CYCLING.

14 THESE IN TURN CAN FEED BACK TO CLIMATE.

15 RIGHT NOW THE UNCERTAINTIES ARE VERY GREAT.
16 WE DON'T HAVE A VERY CLEAR MECHANISTIC UNDERSTANDING,
17 SO WE DEFINITELY NEED MORE
18 RESEARCH. BUT TODAY I'M GOING TO GIVE YOU A FEW
19 EXAMPLES OF HOW ECOSYSTEMS MAY BE IMPACTED IN THE
20 FUTURE UNDER CLIMATE CHANGE.

21 FIRST, I'LL TALK A LITTLE BIT ABOUT THE DECLINE
22 IN ANTARCTIC KRILL, THEN I'LL DISCUSS CORAL BLEACHING AND
OCEAN

23 ACIDIFICATION, AND I'LL END WITH A FEW COMMENTS
24 ON MITIGATION AND ADAPTATION.

25 SO LET'S START DOWN IN THE SOUTHERN OCEAN WITH

0421

1 KRILL. THIS IS THE WORK OF ARGUS ATKINSON, WHO
2 MONITORED A ZOOPLANKTON POPULATION IN THE ATLANTIC
3 SECTOR OF ANTARCTICA. THE WESTERN PENINSULA OF ANTARCTICA
IS

4 ONE OF THE FASTEST WARMING REGIONS ON THE EARTH.

5 IN THIS GRAPH, YOU CAN SEE THAT THE CONCENTRATION OF KRILL
HAS

6 DECREASED OVER THE LAST 25 YEARS. THERE HAS BEEN
7 ABOUT A 50-PERCENT DECREASE IN KRILL

8 ABUNDANCE IN MANY AREAS, AND IT SEEMS TO BE CORRELATED
WITH A LOSS

9 OF WINTER ICE EXTENT IN THE WESTERN PENINSULA. AT
10 THE SAME TIME THAT YOU SEE THESE DECREASES IN KRILL
11 POPULATIONS, YOU ALSO SEE INCREASES IN SALPS, ANOTHER TYPE
12 OF HERBIVOROUS ZOOPLANKTON.

13 SOME PEOPLE HAVE SUGGESTED THAT WE MAY SEE A
14 REGIME SHIFT IN THE FUTURE FROM A KRILL-DOMINATED
15 SYSTEM TO ONE THAT IS DOMINATED BY SALPS. SUCH A CHANGE
16 HAS IMPLICATIONS FOR ANTARCTIC FOOD WEBS BECAUSE
17 KRILL ARE REALLY AT THE CENTER OF ANTARCTIC FOOD WEBS.
18 KRILL ARE NORMALLY VERY ABUNDANT, THEY ARE A VERY
NUTRITIOUS FOOD

19 SOURCE, AND THEY ARE PREY FOR A NUMBER OF HIGHER
20 TROPHIC LEVELS, INCLUDING FISH, PENGUINS, AND WHALES;
21 EVEN THE CRAB-EATER SEAL ACTUALLY EATS KRILL, NOT
22 CRABS.

23 HOWEVER, IF WE GET A SHIFT IN THE REGIME
24 FROM A KRILL-DOMINATED SYSTEM TO ONE DOMINATED BY
25 SALPS, THE FOOD WEB WOULD CHANGE. SALPS ARE GELATINOUS
ORGANISMS. THEIR

0422

1 BODIES ARE ABOUT 96 PERCENT WATER AND THEY ARE A VERY
CARBON-POOR

2 FOOD SOURCE. THEY'RE GENERALLY NOT THE PREFERRED
3 PREY FOR ANY ORGANISM IN A HIGHER TROPHIC LEVEL, AND
4 THEY DON'T LEAD TO HIGHLY PRODUCTIVE FISHERIES. THEY
5 HAVE VERY FAST GENERATION TIMES, SO YOU CAN GET A
6 SALP SWARM IN NO TIME AT ALL. SALPS ARE GENERALLY
7 ASSOCIATED WITH LOWER LATITUDE SYSTEMS RATHER THAN
8 AROUND THE ANTARCTIC WESTERN PENINSULA. AS A CONSEQUENCE,
DETERMINING WHETHER A REGIME SHIFT

IS TAKING PLACE, FROM A KRILL-DOMINATED SYSTEM TO A SALP-
DOMINATED SYSTEM, IS AN AREA OF

9 ACTIVE RESEARCH.

10 LET'S MOVE ON NOW AND TALK ABOUT CORAL
11 BLEACHING. HEALTHY CORALS, SHOWN HERE, ARE RICH IN COLOR.

12 THERE IS A SYMBIOSIS BETWEEN

13 THE CORAL POLYP, WHICH IS AN ANIMAL, AND THE
14 ZOOXANTHELLAE, WHICH ARE PHOTOSYNTHETIC ALGAE THAT
15 LIVE WITHIN THE TISSUES OF THE CORAL POLYP. IF

16 THE SUMMERTIME MAXIMUM TEMPERATURE IS EXCEEDED, THE

17 CORAL POLYP CAN EXPEL ITS ZOOXANTHELLAE AND LEAVE THE
18 CORAL WHITE OR BLEACHED. THE CORAL CAN SURVIVE IN
19 THIS STATE FOR A NUMBER OF WEEKS, BUT IF THE
20 ZOOXANTHELLAE DON'T RETURN TO THE CORALS, THEN CORAL
21 MORTALITY WILL ULTIMATELY RESULT.

22 CORAL BLEACHING WAS FIRST
23 OBSERVED IN THE LATE 1970S, AND IT'S BEEN INCREASING
24 IN ITS OCCURRENCE EVER SINCE THEN. WHAT YOU SEE
25 HERE IS A VERY EXTENSIVE, HEALTHY REEF IN 1995 OFF
0423

1 BELIZE; AND IN 1998, SHORTLY AFTER THE '97-'98
2 EL NINO, WHICH I THINK IS ONE OF THE STRONGEST, IF
3 NOT THE STRONGEST, EL NINO ON RECORD, YOU SEE VERY
4 STRONG EVIDENCE OF MASSIVE BLEACHING IN THE CORALS.
5 WHEN THE INVESTIGATORS WENT BACK IN 1999, THEY
6 FOUND THE CORALS HAD DIED, AND THEY HAD BEEN REPLACED
7 BY GREEN MACROALGAE. THIS CORAL REEF SYSTEM IN BELIZE
8 ESSENTIALLY WAS DECIMATED.

9 NOAA HAS
10 DEVELOPED INDICES OF CORAL BLEACHING BY MAPPING THE
11 SEA SURFACE TEMPERATURE ANOMALIES FROM SATELLITE
12 DATA. A ONE DEGREE HEATING WEEK, DHW, IS WHEN THE
13 TEMPERATURE OF THE WATER IS 1 DEGREE C ABOVE THE
14 MAXIMUM MONTHLY MEAN FOR 1 WEEK. WHEN YOU HAVE
15 4-DEGREE HEATING WEEKS, SHOWN IN THE GREEN COLOR, YOU
16 CAN EXPECT CORAL BLEACHING TO OCCUR. HOWEVER, IF THE
17 TEMPERATURES STAY ELEVATED AND YOU HAVE
18 8-OR-MORE-DEGREE HEATING WEEKS, THEN BLEACHING
19 AND MORTALITY ARE EXPECTED. THAT IS
20 DESIGNATED BY THE YELLOW, GOING INTO THE PINK AND THE
21 PURPLE COLOR.

22 THIS IS A VIDEO FROM THE CARIBBEAN AND
23 THE GULF OF MEXICO FROM 1985 TO 2005. YOU CAN SEE
24 THAT IN THE EARLY YEARS, THERE WAS VERY LITTLE
25 INCIDENCE OF DEGREE HEATING WEEKS. BUT IT INCREASES
0424

1 OVER TIME; AND THEN FINALLY IN 2005, THE EASTERN
2 CARIBBEAN SEA WAS TREMENDOUSLY IMPACTED BY HIGH
3 TEMPERATURES; AND THAT LED TO MASS MORTALITY OF
4 NEARLY 40 PERCENT OF THE ENTIRE CORAL REEF ECOSYSTEM
5 IN THE EASTERN CARIBBEAN. ALMOST 40 PERCENT OF THE
6 ECOSYSTEM DIED IN A SINGLE YEAR.

7 LET'S MOVE ON AND TALK ABOUT OCEAN
8 ACIDIFICATION. THE OCEANS ARE TAKING UP
9 ANTHROPOGENIC CO₂, AND THIS CHANGES SEAWATER
10 CHEMISTRY, AS DICK EXPLAINED. A MODELING

11 STUDY BY CALDEIRA AND WICKETT PROJECTED THAT BY
12 THE END OF THIS CENTURY, BY 2100, THE MEAN PH
13 OF THE SURFACE WATER COULD DROP BY 0.3 TO 0.5 OF A
14 PH UNIT RELATIVE TO THE PRE-INDUSTRIAL VALUE.
15 THIS RATE OF CHANGE IS SIGNIFICANT. IT IS PROBABLY
16 ABOUT A HUNDRED TIMES FASTER THAN THAT WHICH OCCURRED
17 AT THE END OF THE RECENT ICE AGES, AND IT IS PROBABLY
18 TOO FAST TO ALLOW CHANGES IN OCEAN CHEMISTRY TO BE
19 BUFFERED BY THE DISSOLUTION OF CALCIUM CARBONATE
20 SEDIMENTS ON THE SEA FLOOR.

21 WHAT ARE THE IMPACTS OF OCEAN
22 ACIDIFICATION? WE KNOW THE MOST ABOUT THE
23 RESPONSE OF CALCIFIERS TO OCEAN ACIDIFICATION.
24 THESE ARE THE THREE MAJOR GROUPS OF PLANKTONIC
25 CALCIFIERS. AT THE TOP ARE COCCOLITHOPHORES.

0425

1 THESE ARE SINGLE-CELLED ALGAE. THEY PHOTOSYNTHESIZE,
2 AND THE CELL SURFACE IS COVERED WITH CALCIUM CARBONATE
3 PLATES.

4 THE PHOTO BELOW IS A FORAMINIFERAN. THIS IS A PROTIST,
5 ESSENTIALLY LIKE A SHELLED AMOEBA.

6 AND THEN SHOWN BELOW THAT ARE THE PTEROPODS,
7 PLANKTONIC SNAILS THAT SECRETE SHELLS MADE
8 OF ARAGONITE, THE SAME TYPE OF CALCIUM CARBONATE
9 THAT CORALS PRECIPITATE.

10 IN ADDITION TO THESE THREE MAJOR
11 PLANKTONIC GROUPS, THERE IS ALSO A DIVERSE SUITE
12 OF BENTHIC CALCIFIERS: THE CORALS THAT
13 WE'VE ALREADY TALKED ABOUT INCLUDING HARD CORALS AND SOFT
14 CORALS; MANY DIFFERENT TYPES OF MOLLUSCS INCLUDING
GASTROPODS,

15 AND BIVALVES - MANY OF THESE ARE VERY IMPORTANT TO
16 COMMERCIAL FISHERIES AND ALSO ARE IMPORTANT IN
17 AQUACULTURE WORLDWIDE. OTHER BENTHIC CALCIFIERS INCLUDE
18 SEA URCHINS AND CORALLINE RED ALGAE WHICH SECRETE CALCIUM
CARBONATE

19 IN THE FORM OF HIGH-MAGNESIUM CALCITE. THIS TYPE OF CALCIUM
CARBONATE
20 IS VERY SOLUBLE IN SEAWATER. IN ADDITION, SOME CRUSTACEANS,
21 THE DECAPODS SUCH AS CRABS AND LOBSTERS, HAVE VERY HARD
SHELLS WHICH

22 CONTAIN A CALCIFIED LAYER. MANY OF THESE BENTHIC ORGANISMS
HAVE

23 PLANKTONIC LARVAL STAGES THAT ALSO CALCIFY. WE
24 THINK THAT PLANKTONIC LARVAL STAGES COULD
25 BE PARTICULARLY VULNERABLE TO

0426

1 DECREASING PH IN THE OCEANS.

2 THUS FAR, CORAL REEFS HAVE BEEN MOST STUDIED IN
EXPERIMENTS INVESTIGATING
THE IMPACTS OF OCEAN ACIDIFICATION.

3

4 THESE DATA ARE FROM THE WORK OF CHRIS LANGDON, WHO DID A
5 NUMBER OF EXPERIMENTS WITH CORALS IN THE LAB AND ALSO
6 IN THE BIOSPHERE 2 MESOCOSM. HERE HE HAS PLOTTED
7 THE RESPONSE OF 12 DIFFERENT SPECIES OF
8 REEF-CALCIFYING ORGANISMS AS A FUNCTION OF THE
9 CARBONATE ION CONCENTRATION, SHOWN ON THE X-AXIS.

10 WE'VE ALSO PLOTTED ON THIS GRAPH THE
11 CORRESPONDING ATMOSPHERIC CO₂ CONCENTRATION. WHAT
12 WE FIND IS THAT AT HIGH CARBONATE ION
13 CONCENTRATIONS, REEF ORGANISMS HAVE HEALTHY, VERY GOOD
14 CALCIFICATION RATES. CALCIFICATION RATES DECLINE LINEARLY
15 WITH DECREASING CARBONATE ION CONCENTRATION.
16 WHEN THE CARBONATE CONCENTRATION DECLINES
17 TO ABOUT 150 MICROMOLAR, THEN NET
18 DISSOLUTION OCCURS. NOW, THIS NUMBER IS A LITTLE
19 UNCERTAIN. NET DISSOLUTION MIGHT OCCUR AT SLIGHTLY HIGHER
OR LOWER
20 CARBONATE ION CONCENTRATIONS, BUT WHEN IT DECLINES BELOW
21 ABOUT 110 TO 150 MICROMOLAR, THESE DATA SUGGEST THAT
22 NET DISSOLUTION OF THE REEF WILL RESULT. AND 150 MICROMOLAR
23 CORRESPONDS TO AN ATMOSPHERIC CO₂ CONCENTRATION OF
24 ABOUT 550 PPM.

25 THIS IS THE CLEAREST EXAMPLE THAT WE

0427

1 HAVE OF A TIPPING POINT IN MARINE SYSTEMS. AND IT
2 BEGS THE QUESTION: CAN CORALS SURVIVE
3 DECREASED CARBONATE ION CONCENTRATION AND LOWER PH?

4 IN A RECENT STUDY, FINE &
5 TCHERNOV GREW TWO DIFFERENT SPECIES OF
6 CORALS IN CORROSIVE WATER, THE PH WAS ABOUT 7.3 TO
7 7.6, FOR A YEAR. THE CORALS
8 STARTED LIKE THIS -- AND AFTER A MONTH IN THAT
9 CORROSIVE SEAWATER, THE SKELETON COMPLETELY
10 DISSOLVED, AND THE CORAL COLONY DISASSOCIATED INTO
11 INDIVIDUAL POLYPS, WHICH THEN LOOKED VERY MUCH
12 LIKE ANEMONES. AFTER 11 MONTHS, FINE AND
13 TCHERNOV PUT THE POLYPS BACK INTO NORMAL SEAWATER;
14 AND THE POLYPS STARTED TO RECALCIFY AND REAGGREGATE INTO
15 A COLONY.

16 THESE RESULTS ARE VERY INTERESTING. THE CORALS WERE
NOT
17 ABLE TO CALCIFY AT LOW PH, BUT THEY DID SURVIVE. THIS STUDY
WAS DONE
18 IN THE LAB. WHAT DOES IT MEAN FOR THE FIELD? IN THIS LAB STUDY,
THERE
19 WAS NO PREDATION. IF WE CAN ASSUME THAT A CARBONATE
SKELETON
20 PROVIDES SOME BENEFIT TO THE ORGANISM, SOME
21 PROTECTION FROM PREDATORS, THESE NAKED POLYPS THAT
RESULTED IN THE
22 THE LAB PROBABLY WOULD NOT SURVIVE OUT IN THE OPEN IN THE
FIELD.

23

24 THEY WOULD HAVE TO LIVE CRYPTICALLY IN
25 CREVICES, HIDDEN FROM PREDATORS, OR THEY

0428

1 WOULD BE EATEN. IN ADDITION, THE ABSENCE OF CORAL
CALCIFICATION MEANS THERE IS THE LOSS OF THAT
2 THREE-DIMENSIONAL REEF STRUCTURE THAT IS SO IMPORTANT
3 AND ENABLES REEF SYSTEMS TO HAVE VERY HIGH
4 BIODIVERSITY. FINALLY, IN THE ABSENCE OF CORAL CALCIFICATION,
YOU WOULD ALSO GET CHANGES IN THE
5 ECOSYSTEM SERVICES THAT REEFS SUPPLY.

6 LET'S TURN NOW TO THE PLANKTON, WHERE
7 CALCIFICATION ALSO PLAYS A VERY IMPORTANT ROLE.
8 THIS IS FROM A LANDMARK STUDY BY ULF
9 RIEBESELL AND HIS COLLEAGUES. THEY LOOKED AT THE
10 COCCOLITHOPHORES. THESE ARE THE SINGLE-CELLED ALGAE
11 THAT PHOTOSYNTHESIZE AND MAKE CALCIUM CARBONATE
12 PLATES. THESE ARE TWO DIFFERENT SPECIES OF
13 BLOOM-FORMING COCCOLITHOPHORES. THEY'RE VERY
14 ABUNDANT, AND THE BLOOMS THAT THESE SPECIES FORM CAN BE
SEEN
15 IN SATELLITE IMAGES. WHEN RIEBESELL AND HIS CO-WORKERS
GREW
16 THESE SPECIES IN THE LAB UNDER CONDITIONS OF ELEVATED CO₂,
THEY FOUND THAT
17 CALCIFICATION DECREASED. THIS SPECIES, GEPHYROCAPSA
OCEANICA, WAS
18 PARTICULARLY SENSITIVE AND ITS CALCIFICATION RATE
19 DECREASED BY ALMOST 50 PERCENT WHEN PCO₂ WAS ELEVATED TO
780-850 PPMV.

20 BUT NOT ALL COCCOLITHOPHORES RESPOND IN THE
21 SAME WAY. TWO ADDITIONAL SPECIES HAVE BEEN INVESTIGATED
22 TO DATE, AND ONE OF THESE SPECIES WAS NOT SENSITIVE TO

23 INCREASED PCO₂. CURRENTLY, THAT SINGLE SPECIES OF
COCCOLITHOPHORE
24 IS THE ONLY EXAMPLE WE HAVE OF A
25 CALCIFYING ORGANISM THAT IS NOT SENSITIVE TO ELEVATED
0429

1 PCO₂. BUT I NEED TO TELL YOU THAT WE HAVE JUST
2 SCRATCHED THE SURFACE. WE HAVE INVESTIGATED SO FEW
3 SPECIES, SO FEW TAXA, THAT WE CAN'T MAKE
4 GENERALITIES AT THIS POINT.

7 THE PTEROPODS ARE ANOTHER IMPORTANT
8 PRODUCER OF CALCIUM CARBONATE IN THE PLANKTON, AND
9 THEY ARE WIDELY DISTRIBUTED THROUGHOUT THE WORLD'S
10 OCEANS. THEY ARE VERY ABUNDANT AT HIGH
11 LATITUDES. IN POLAR AND SUBPOLAR REGIONS, THEIR
12 POPULATIONS CAN OCCUR IN VERY HIGH NUMBERS, WITH DENSITIES
GREATER THAN
13 1000 INDIVIDUALS PER CUBIC METER.
14 WHEN PTEROPODS OCCUR IN SUCH HIGH NUMBERS, THEY ARE GOING
TO BE AN
15 IMPORTANT FOOD SOURCE FOR A VARIETY OF DIFFERENT
16 PREDATORS. DATA FROM THE NORTH PACIFIC SUGGEST THAT
PTEROPODS
17 MAY BE VERY IMPORTANT IN SOME YEARS TO THE RECRUITMENT
18 AND ADULT BIOMASS OF SALMON, POLLOCK, AND SOME OTHER
19 COMMERCIALY IMPORTANT FISH.
20 ON REGIONAL SCALES, PTEROPODS MAY ALSO AFFECT THE
GEOCHEMICAL
21 CYCLES OF CARBON AND SULFUR, AS THEY
22 CONCENTRATE DIMETHYL SULFIDE. WHEN WE PUT
23 LIVE PTEROPODS IN SEAWATER WITH LOWER CALCIUM
24 CARBONATE ION CONCENTRATION - A CONCENTRATION THAT WOULD
CORRESPOND TO
25 THE SEAWATER CONDITIONS THAT ARE PROJECTED TO OCCUR AT
HIGH LATITUDES

0430

1 BY THE YEAR 2100 - THE SHELLS OF THE
2 ANIMALS STARTED TO DISSOLVE WITHIN 48 HOURS. THE
3 ANIMALS WERE STILL ACTIVELY SWIMMING, BUT THEIR
4 SHELLS WERE DISSOLVING. AT LEAST IN THE SHORT
5 TERM, IT DOESN'T APPEAR THAT PTEROPODS HAVE ANY MECHANISMS
6 TO PROTECT THEM FROM DISSOLUTION. THEIR SHELLS ARE
7 VERY THIN, ON THE ORDER OF 7 MICROMETERS
8 THICK, AND THEY WILL DISSOLVE RAPIDLY UNDER CORROSIVE
CONDITIONS.

9 IN THE HIGH LATITUDES, PTEROPODS APPEAR TO HAVE

10 VERY LONG GENERATION TIMES. THEY MAY HAVE A
11 GENERATION TIME OF ABOUT 1 TO 2 YEARS. AS A CONSEQUENCE,
HIGH LATITUDE PTEROPODS
12 DO NOT HAVE MANY OPPORTUNITIES TO DEVELOP NEW
13 MECHANISMS OF COPING WITH OCEAN ACIDIFICATION BEFORE 2100.
14 THERE IS ADDITIONAL EVIDENCE FOR OTHER
15 IMPACTS OF OCEAN ACIDIFICATION ON ECOSYSTEMS AND
16 ORGANISMS. STUDIES REVEAL THAT THERE ARE ADVERSE EFFECTS
ON
17 REPRODUCTIVE SUCCESS, FOR EXAMPLE, IN SEA URCHINS,
18 BIVALVES, COPEPODS AND FISH LARVAE. OTHER STUDIES INDICATE
THERE IS
19 REDUCED GROWTH IN ADULTS, APART FROM THE
20 CALCIFICATION EFFECTS THAT WE'VE JUST DISCUSSED.
21 WE SEE REDUCED GROWTH IN ADULT SEA URCHINS AND
22 BIVALVES, FOR EXAMPLE.
23 ELEVATED CO₂ CAN ALSO IMPAIR THE OXYGEN
24 TRANSPORT OF THE BLOOD PIGMENT IN SQUID. HIGH PCO₂ ALSO
25 APPEARS TO REDUCE THE SCOPE OF ACTIVITY IN SQUIDS.

0431

1 THERE ARE SEVERAL RECENT PAPERS THAT
2 REPORT INCREASED RATES OF NITROGEN FIXATION UNDER HIGH CO₂
CONDITIONS,
3 AND THIS COULD HAVE VERY SWEEPING,
4 LARGE-SCALE CHANGES IN ALGAL ABUNDANCE AND NUTRIENT
5 LIMITATION IN SOME SUBTROPICAL AREAS, WHICH COULD RESULT IN
MAJOR
6 REORGANIZATION OF SUCH ECOSYSTEMS.

7

9 MOVING ON TO MITIGATION, AS WE HAVE ALL
10 HEARD DURING THE LAST TWO DAYS, WE NEED TO
11 DECREASE CO₂ EMISSIONS.

12 OTHER MITIGATION
13 STRATEGIES THAT ARE FOCUSED ON THE OCEAN
14 INCLUDE IRON FERTILIZATION, DIRECT INJECTION
15 OF CO₂, AND SEAWATER ELECTROLYSIS. THERE ARE A FEW OTHER
16 IDEAS OUT THERE, AND ALL OF THESE OPTIONS HAVE PROS AND CONS
17 ASSOCIATED WITH THEM.

18 THERE IS THIS SENSE OF URGENCY. SOME
19 PEOPLE HAVE SAID WE HAVE ONLY A 10-TO-20-YEAR WINDOW
20 TO MAKE SUBSTANTIAL CHANGES. THAT ESTIMATE WAS IN THE
STERN
21 REPORT AND WAS ALSO SUGGESTED BY JIM HANSEN IN A RECENT NAS
PAPER.

22 NOW, WHAT ABOUT ADAPTATION AND COPING
23 STRATEGIES? THE BEST EXAMPLE WE HAVE

24 IS THE "REEF MANAGER'S GUIDE TO CORAL
25 BLEACHING." THIS JUST CAME OUT IN THE LAST YEAR
0432

1 AND IS THE PRODUCT OF A COLLABORATION BETWEEN NOAA,
2 THE EPA, AND THE AUSTRALIA GREAT BARRIER REEF PARK
3 AUTHORITY. THIS GUIDE PROVIDES CORAL REEF
4 MANAGERS WITH SOME STRATEGIES THAT THEY CAN USE TO
5 TRY TO PROTECT THEIR REEFS DURING THOSE HIGH-DEGREE
6 HEATING WEEKS, THOSE CONTINUOUS WEEKS OF ELEVATED
7 TEMPERATURE. ONE OF THE SUGGESTIONS IS TO
8 PUT OUT SHADE CLOTH OVER CERTAIN
9 AREAS OF THE REEF. OBVIOUSLY, THIS IS A VERY
10 SMALL-SCALE, LOCALIZED COPING STRATEGY.
11 OTHER SUGGESTIONS INVOLVE TRYING TO DECREASE OR
12 LIMIT OTHER STRESSORS, SUCH AS FISHING OR HUMAN
13 ACCESS TO THAT REEF. IN OTHER WORDS, TRY TO CONTROL WHAT
14 YOU CAN
15 TO PROVIDE THE CORALS A BETTER CHANCE OF SURVIVING THOSE
16 ELEVATED TEMPERATURE PERIODS.
17 ANOTHER IDEA THAT HAS BEEN SUGGESTED
18 IS TO REAR THE POTENTIALLY VULNERABLE
19 JUVENILE STAGES OF ORGANISMS UNDER CONTROLLED CONDITIONS,
20 IN A
21 LABORATORY OR AN AQUACULTURE FACILITY, FOR EXAMPLE; AND
22 THEN AFTER
23 THE ORGANISMS HAVE GROWN TO A LARGER SIZE THAT MAY BE
24 MORE RESISTANT TO ELEVATED PCO₂,
25 YOU CAN RELEASE THEM IN THE FIELD.
26 ALSO, YOU COULD REPOPULATE IMPACTED AREAS
27 WITH RESISTANT SPECIES.
28 NOW, THE PROBLEM WITH THESE LAST TWO IDEAS
29 IS THAT THEY ARE MERELY SUGGESTIONS AT THIS TIME.
0433

1 WE DON'T HAVE ENOUGH INFORMATION OR A SUFFICIENT
2 UNDERSTANDING
3 OF THE IMPACTS AND THE MECHANISMS INVOLVED TO
4 ACTUALLY DEVELOP EFFECTIVE COPING STRATEGIES AT THIS
5 POINT. SO, AGAIN, RESEARCH IS CLEARLY REQUIRED.
6 WHERE SHOULD WE GO FROM HERE? IN MY
7 VIEW, THERE ARE SEVERAL RESEARCH CHALLENGES AHEAD OF
8 US. IF WE ARE TO MAKE SIGNIFICANT PROGRESS IN MANY AREAS, IT
9 IS GOING TO REQUIRE MULTI-DISCIPLINARY AND INNOVATIVE
10 APPROACHES. SOME OF THE PARTICULARLY DIFFICULT ISSUES THAT
11 WILL NEED TO BE RESOLVED OVER
12 THE LONG-TERM INCLUDE THE FOLLOWING.
13 FIRST, WE NEED TO DEVELOP METHODS TO

11 INVESTIGATE THE RESPONSE OF ORGANISMS THAT WE CAN'T
12 MAINTAIN IN THE LAB. WE NEED TO BE ABLE TO INVESTIGATE
13 THEM IN THE FIELD UNDER FIELD CONDITIONS. THIS INCLUDES
ORGANISMS SUCH AS
14 FORAMINIFERA, PTEROPODS, AND SQUID. WE CAN'T CULTURE
15 THOSE IN THE LAB AND, TO DATE, WE HAVE ONLY BEEN ABLE
16 TO DO VERY SHORT-TERM EXPERIMENTS. WHILE SUCH EXPERIMENTS
PROVIDE
17 VITAL DATA AND ARE CRITICAL TO CONDUCT AT THIS STAGE OF
OCEAN ACIDIFICATION RESEARCH,
WE ULTIMATELY WOULD WANT TO DO EXPERIMENTS WITH THE ADDED
COMPLEXITIES AND THE DIVERSITY OF SPECIES AT
MULTIPLE TROPHIC LEVELS THAT ARE PRESENT IN ECOSYSTEMS.
19 WE ALSO NEED TO IDENTIFY THE SUBLETHAL
20 EFFECTS OF LONG-TERM, CHRONIC EXPOSURE TO ELEVATED PCO2.
21 IF YOU'RE DOING A
22 PERTURBATION EXPERIMENT, YOU'RE GOING TO PUT AN ORGANISM IN
23 ELEVATED PCO2. EVEN IF YOU ACCLIMATE THE ORGANISM FOR A
PERIOD
24 OF WEEKS OR MONTHS, THAT'S STILL NOT WHAT'S GOING TO
25 ACTUALLY HAPPEN IN THE FIELD OVER A PERIOD OF DECADES AND
OVER THE

0434

1 NEXT CENTURY. THIS IS A BIG CHALLENGE. HOW CAN WE
2 ADDRESS WHETHER SPECIES WILL BE ABLE TO ADAPT? HOW CAN WE
DETERMINE THE
3 CAPACITY OF A SPECIES TO ADAPT OVER TIME SCALES OF DECADES TO
CENTURIES?

4 FINALLY, WE NEED TO BE ABLE TO
5 DEVELOP A PREDICTIVE UNDERSTANDING OF FUTURE CHANGES
6 TO ECOSYSTEMS SO THAT EFFECTIVE COPING STRATEGIES
7 CAN BE DEVELOPED.

8

9 THANK YOU FOR YOUR ATTENTION.
