# The Cape Verde Atmospheric Observatory (CVO)

Observatory established in 2006 as global GAW station.

Only GAW global station continuously measuring NO & NO<sub>2</sub> in the tropics & at a background site.

Other measurements: O<sub>3</sub>, CO, CH<sub>4</sub>, CO<sub>2</sub>, N<sub>2</sub>O, NMHCs, DMS, O-VOCs, Halocarbons, Mercury, Meteorology, Aerosol, Spec-Rad.

# NO<sub>x</sub> measurements at Cape Verde

Custom dual channel NO chemiluminescence instrument.

**Channel 1:** NO and NO<sub>x</sub> by selective photolytic dissociation of NO<sub>2</sub> @ 395nm or 385nm (since March 2015)

**Channel 2:** NO<sub>y</sub> 4 channel thermal dissociation NO<sub>y</sub> (ΣPANs, ΣANs, HNO<sub>3</sub>, Σreactive nitrogen.)

**LODs;** NO ~0.3 ppt, NO<sub>2</sub> ~ 0.35 ppt, NO<sub>y</sub> ~ 5 ppt / hour.

**Calibrated:** Sensitivity,  
NO<sub>2</sub> converter efficiency,  
artifact NO/NO<sub>2</sub> signals on both channels.  
Pre-reactor zero signal every 5 minutes

**NO<sub>x</sub>** measuring near continuously since October 2006.

**NO<sub>y</sub>** until 2009,

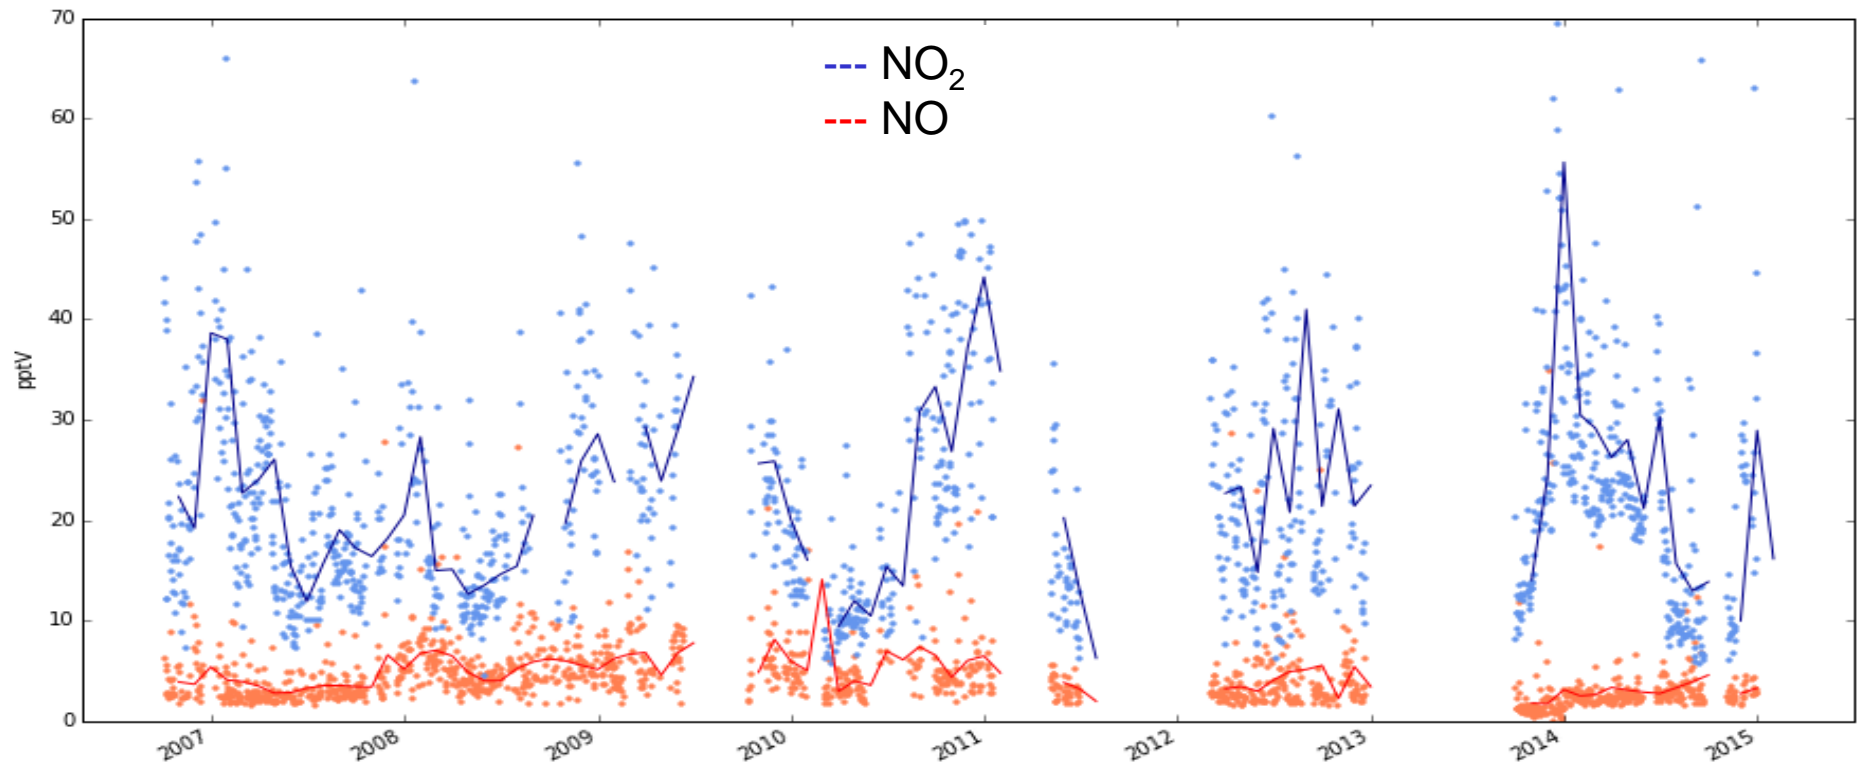

**Speciated NO<sub>y</sub>** since 2015 – only one anywhere!

Original single channel instrument from 2006 – 2009, upgraded to dual channel 2009 – present. Air Quality Design, inc. Golden, Colorado, USA

# NO<sub>x</sub> time series

- Typically very low mixing ratios of NO<sub>x</sub>; 10 – 50 pptv leading to net ozone destruction

Typically a winter/spring time maximum in NO<sub>x</sub> dominated by NO<sub>2</sub>.

NO<sub>2</sub> consistently higher than photo-stationary steady state would predict.

# NO and NO<sub>2</sub> consistency with theory

Daily ozone destruction predicted in a box model constrained to observed NO.

Model prediction of O<sub>3</sub> loss at the different NO concentration observed is consistent with the observed O<sub>3</sub> losses

Supports the NO observations

Model prediction for NO<sub>2</sub> concentrations are significantly lower than those observed.

NO:NO<sub>2</sub> observed 1 : 4 - 8

NO:NO<sub>2</sub> simulated 1 : 2

# NO<sub>2</sub> diurnal behaviour

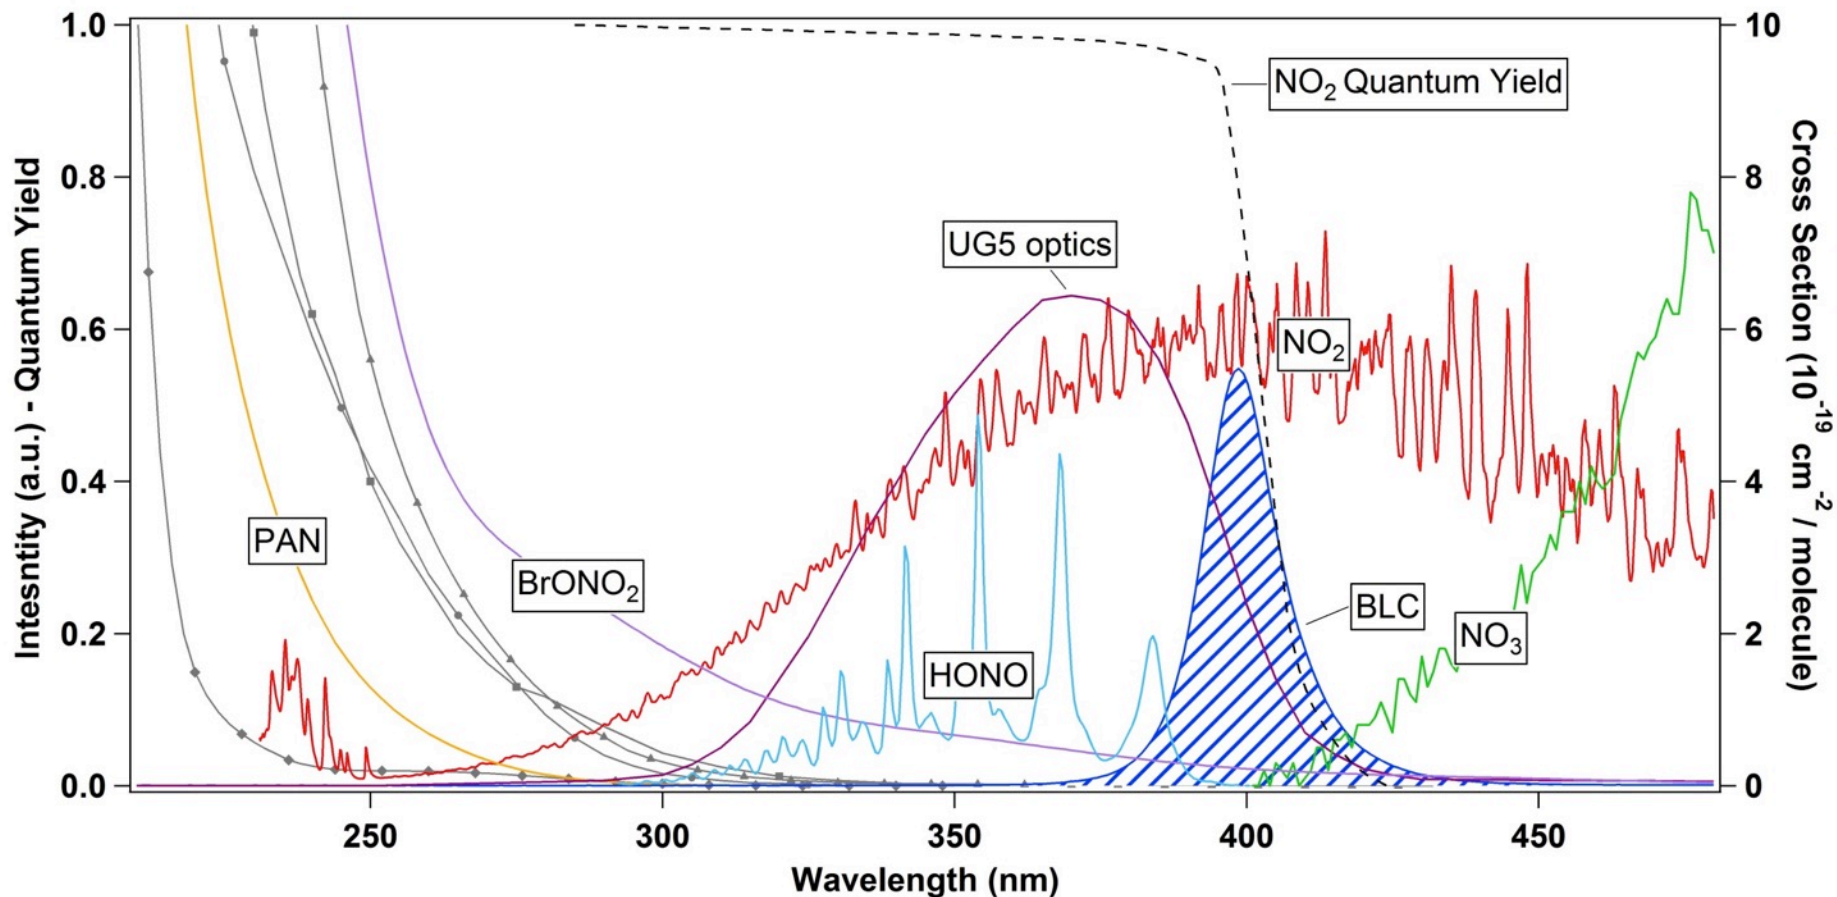

Similar discrepancy seen between GEOS-Chem model and measurements

Night time concentrations are simulated well but diurnal signal in model and measurements are significantly different.

<sup>1</sup> GEOS-Chem model output courtesy of Tomas Sherwen

# Possible NO<sub>2</sub> measurement error

Photolytic converter:

Minor overlap with HONO, nitrate and BrONO<sub>2</sub> absorbance bands.

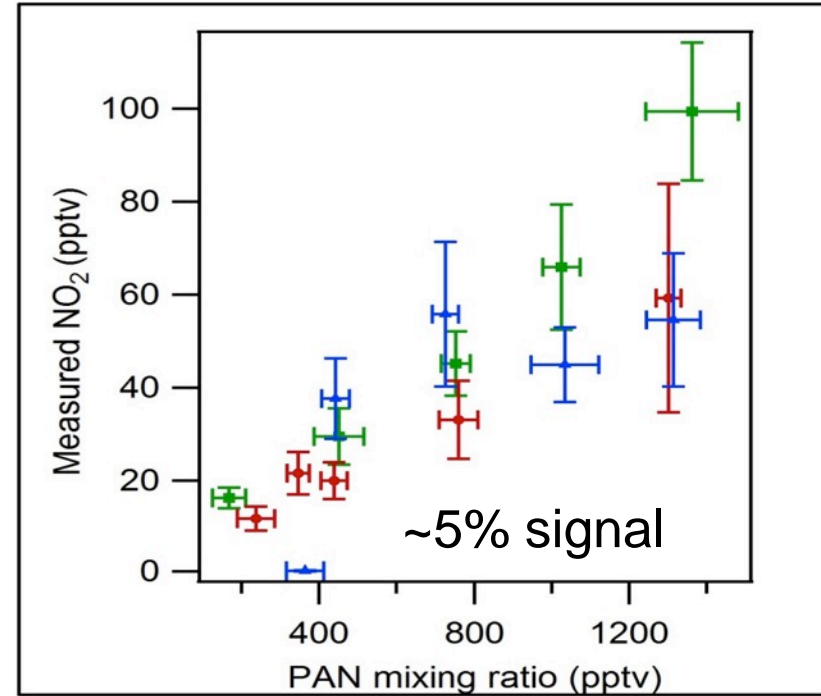

Not expected to be major contributors at Cape Verde.

# Possible NO<sub>2</sub> measurement error

Modelled PAN thermal decomposition

Measured NO<sub>2</sub> signal from PAN

Heat!

NO<sub>2</sub>\* more easily photolysed.

Proportionately greater contribution to NO<sub>2</sub> signal.

Higher conversion efficiency and lower temperature to reduce the error.

# NO<sub>y</sub> speciation measurements

NO<sub>y</sub> species a reservoir for NO<sub>x</sub>

Likely source of NO<sub>2</sub> at Cape Verde

Partitioning between gas and particulate phase necessitates speciation measurement.

NO<sub>y</sub> inlet mounted on 10m tower

3 heated quartz furnaces

1 molybdenum catalyst

Switchable cyclone

<sup>1</sup> <http://www.leos.le.ac.uk/group/mpb/images/trop5.png>

# NO<sub>y</sub> speciation measurements

NO<sub>x</sub> from thermal decomposition of NO<sub>y</sub> species detected quantitatively.

**ΣPANs**

**ΣANs**

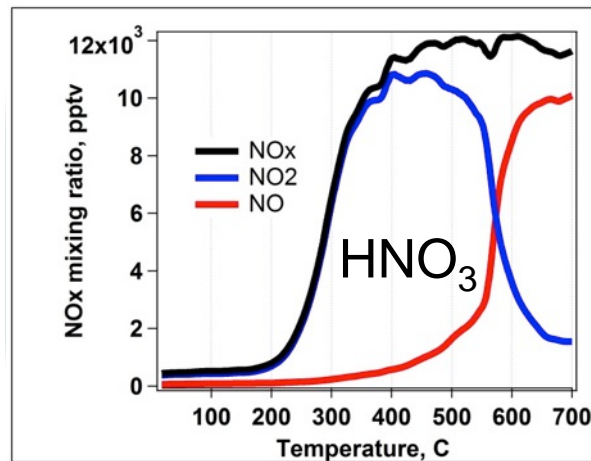

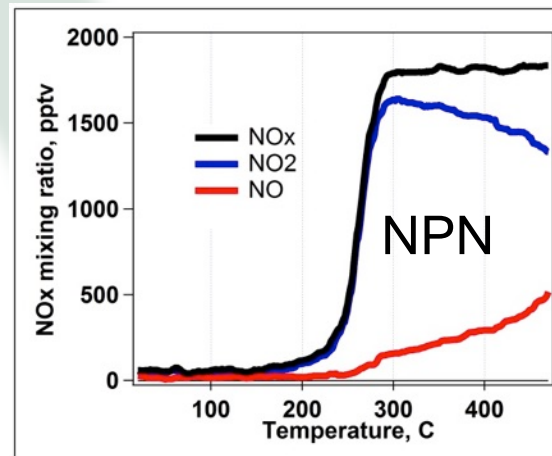

**HNO<sub>3</sub>**

NO and NO<sub>2</sub> observed

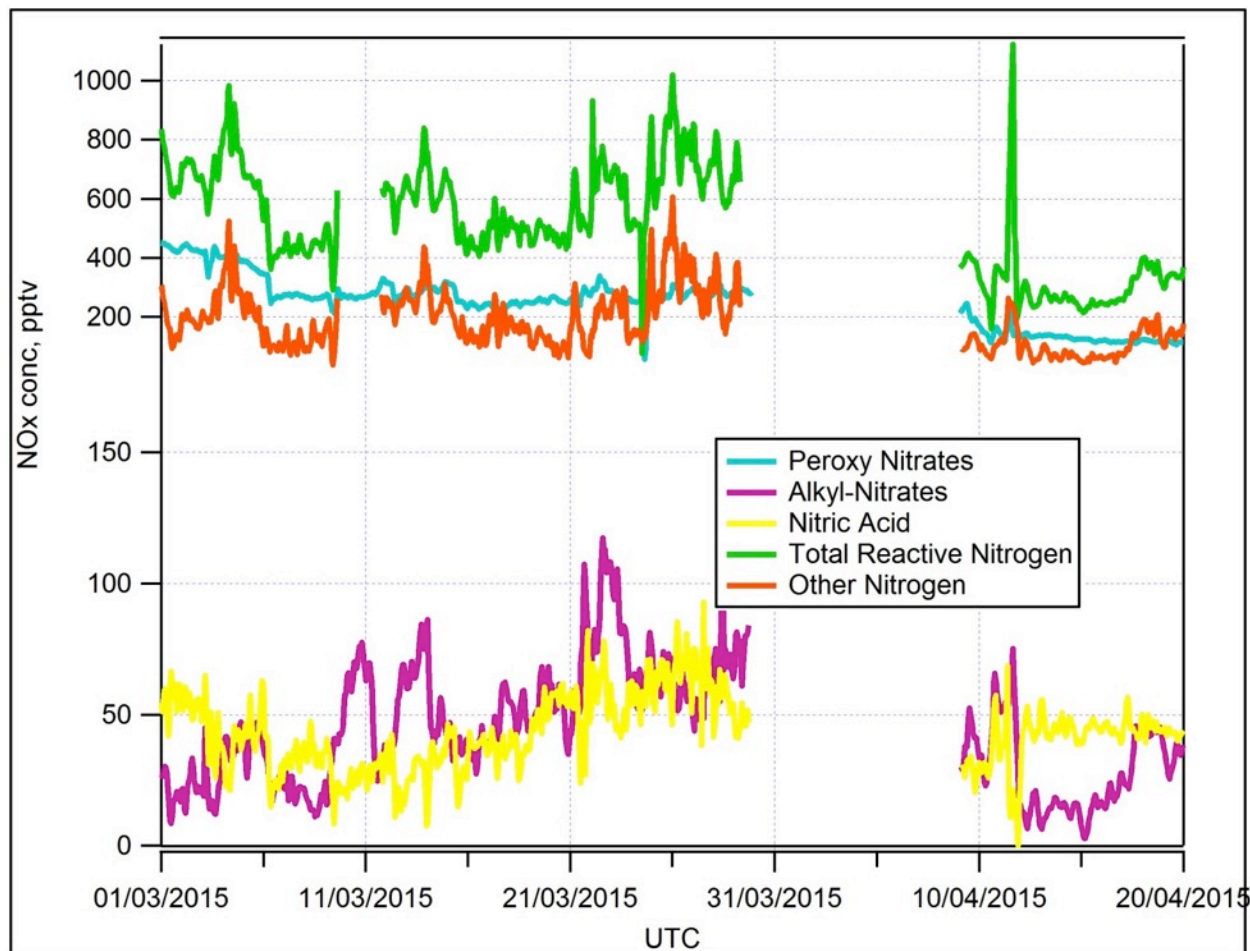

Inter-conversion  
conserves NO<sub>x</sub>

Need to measure both

# NO<sub>y</sub> speciation measurements

Time series shows a seasonal decrease from winter to spring in total NO<sub>y</sub> – especially in ‘PANs’.

‘PANs’ range 150 – 450 ppt. 30 – 50% of NO<sub>y</sub> unaccounted for.

# Conclusions and Outlook

## Conclusions:

- Surprisingly large contribution of 'PANs' or other thermally labile compounds which may also be readily photolysed producing  $\text{NO}_2$  during the day.
- Possible interference from thermally labile compounds causing overall offset in  $\text{NO}_2$ .
- $\text{NO}_2$  diurnal necessitates daytime production of  $\text{NO}_2$  in-situ.

## Outlook:

- Inclusion of particulate nitrate measurement will better inform what makes up the difference between the nitric acid measurement and total reactive nitrogen.
- $\text{NO}_2$  measurement can still be improved in terms of potential interference.
- Inclusion of  $\text{NO}_y$  data in model to try and reproduce observed diurnal.
